

REMARKS

This amendment is to eliminate multiple-dependent claims and otherwise place the application in better condition for examination and prompt allowance.

An early allowance of claims 1-8 (all claims) is requested.

EVACUATION DEVICE

EVACUATING DEVICE

Background

The invention relates to an evacuation devices ~~with the features of the preamble of Claim 1.~~

If in a process chamber, or in any other vacuum chamber, pressures are
5 supposed to be generated which lie in the high vacuum range ($\leq 10^{-3}$ mbar), it is customary to use evacuation devices with a suction-side vacuum pump and an atmospheric pressure-side vacuum pump (backing vacuum pump). The suction-side vacuum pump is, as a rule, ~~formed as~~ a mechanical, kinetic vacuum pump. Among these are gas ring vacuum pumps and turbo vacuum pumps (axial, radial) as well as
10 molecular and turbomolecular vacuum pumps.

At pressures of said type the gases to be conveyed behave molecularly, that is, in such a way that a directed flow can only be achieved by pump structures which give the individual gas molecules pulses with a preferred direction, the desired direction. Since the gas molecules in the chamber to be evacuated have no preferred
15 direction, only those gas molecules get into the suction nozzles of the connected vacuum pump which randomly have this direction of motion.

From [[EP 363 503 A1]] US 4,978,276, an evacuation device of the type relevant here is known. The rotor and stator of the mechanical-kinetic vacuum pump are formed to be cylindrical. In order to achieve the result that as many gas
20 molecules as possible go into the suction nozzles of the vacuum pump connected to the chamber, i. e. the suction-side vacuum pump, the rotor has a conical hub whose diameter increases in the direction of the pressure side. The width of the webs between the hub and the cylindrical inner face of the stator decreases accordingly in the direction of the pressure side. This realization has the advantage that the inlet
25 cross-section for the gases behaving molecularly, i.e. the suction-side annular surface in which the gases to be conveyed enter, is relatively large. An evacuation device of the known type is thus particularly suitable for those applications in which there is a demand for high gas throughputs.

The objective of the present invention is to further improve an evacuation device of the type relevant here with respect to the demand for high gas through puts.

~~This objective is realized by the characterizing features of the claims.~~

5

Summary

~~Selety due to the fact that~~ At the suction-side annular surface, in which the gases behaving molecularly enter[[,]] ~~in the pump according to the invention lies[[,]] in the radial direction[[,]]. further out, an~~ An enlargement of the inlet cross-
10 section is achieved, even in the case of a cylindrical structure of the rotor hub, since the inlet cross-section increases quadratically with the radius ~~of the outer rotor geometry~~. Furthermore, the radially outwards-shift outermost edges of the rotor's components (webs) effecting the gas conveyance ~~has~~ have, as a consequence, higher circumferential speeds, whereby the gas throughput is further increased.

15

It is particularly advantageous if the hub is structured conically[[,]] ~~as in the evacuation device according to the state of the art~~. In the case of an evacuation device formed in this way the inlet cross-section is ~~greater by a multiple than in the state of the art~~.

20

Finally, it is advantageous if the lines, which represent the form of the outer diameter of the rotor as well as the inner diameter of the stator in a longitudinal section through the suction-side vacuum pump, run in the form of a curve arched inwards in such a manner that the slope of the curves ~~{sie}~~ increases from the suction side to the pressure side. It is particularly expedient if these lines have essentially the form of a hyperbola. This structure of the suction-side vacuum pump ensures an
25 optimal and, above all, disruption-free flow of the conveyed gases ~~conveyed~~ and thus contributes ~~essentially to the goal of the improvement of the gas throughput~~. In all, an ~~essential~~ improvement of the capacity density is achieved, that is, that the ratio of the capacity of the suction-side vacuum pump to its mass is ~~essentially~~ greater than in the state of the art.

30

~~Further advantages and details of the invention are intended to be explained with the aid of embodiment examples represented schematically in Figures 1 to 4.~~

Shown are:

Still further advantages of the present invention will be appreciated to those of ordinary skill in the art upon reading and understand the following detailed description.

Brief Description of the Drawings

The invention may take form in various components and arrangements of components, and in various steps and arrangements of steps. The drawings are only for purposes of illustrating the preferred embodiments and are not to be construed as limiting the invention.

Figure 1 is a section through a realization an embodiment with a conical stator and a cylindrical rotor hub,

Figure 2 is a section through a realization an embodiment with a conical stator and a conical rotor hub,

Figure 3 is a section through a realization an embodiment with a stator arched inwards and a rotor hub arched outwards,

Figure 4 a realization an embodiment according to Figure 3 in which the rotor is represented in a perspective view.

Detailed Description

In the figures Figures, the device according to the invention is denoted by 1[[]], the The suction-side vacuum pump is denoted by 2[[]], and the The atmospheric pressure-side vacuum pump, only represented as a symbol symbolically, is denoted by 3. The suction-side pump 2 is formed as a mechanical-kinetic vacuum pump. It comprises a three-part housing 4 with the sections 5, 6, and 7. The suction-side section 5 is provided with a flange 8 which forms the a suction aperture 9 and serves for the connection to a system to be evacuated. Its inner wall 10 forms the stator component of the mechanical-kinetic vacuum pump 2. The housing section 5 encircles the a rotor 11. This comprises a hub 12, which carries on its outer side the structure 13 effecting which effects the gas conveyance. This structure consists of webs 14 (ef., in particular, Figure 4) whose pitch and width decrease from the suction

side to the pressure side, ~~as is known, for example, from~~ [[EP 363 503 A1]]. The axis of rotation of the rotor 11 is denoted by 15. Between the outer contour of the rotor 11 and the stator, i. e. the inner wall 10 of the housing 4, there is a gap 16, which should be as small as possible to avoid significant back-flows.

5 The housing section 5, structured, at least on its inner side, conically, is supported on the central, essentially cylindrical housing section 6. A lower end section 18 of the lower part of the housing section 5 projects into the housing section 6, and, in fact, up to the pressure-side end of the rotor 11. The gases conveyed by the rotor 11 and by the stator ~~{sic}~~ [[8]] 10 arrive in an annular chamber 19, to which the
10 an outlet nozzle 21 is attached. This is connected to the atmospheric pressure-side vacuum pump 3 via the line 22.

 The hub 12 is ~~formed to be~~ hollow. In the area of the suction side it ~~comprises~~ includes a disk 23 which separates the a pressure-side cavity 24 in the hub 12 from the suction side.

15 The lower housing section 7 is formed to be somewhat vat-shaped and is fastened to the central housing section 6. Together with the pressure-side cavity 24 in the hub 12, it forms a motor and bearing area. In Figures 1 to 3 a drive motor and bearings for the rotor are not represented in detail. These components are known per se. The bearings preferably are ~~consists expediently of~~ magnetic bearings. They
20 are particularly suitable for mechanical-kinetic vacuum pumps due to their high rotary speeds. Those parts of the drive and bearing system which project into the housing section 7 are represented in Figure 4. A brake 25 for cases of lubrication failure and components 26 of a brake for cases of ~~turbulence~~ ~~{sic}~~ (?) instability can be seen.

 In the ~~realizations~~ embodiments according to Figures 1 and 2, the outer
25 contour of the rotor 11 and the stator 10 inner surface of the housing 2 are formed to be conical and, in fact, in such a manner that the diameters of the outer contour of the rotor and of the stator decrease from the suction side to the pressure side. Thereby the desired increase of the inlet cross-section for the molecules to be removed from the connected vacuum chamber as well as the circumferential speed of the structure 13 is
30 achieved. In the embodiment according to Figure 2 the hub 12 of the rotor 11 is also formed to be conical, and, in fact, in such a manner that the hub diameter increases

from the suction side to the pressure side. The inlet surface for the molecules to be conveyed is enlarged by this measure.

In the case of the embodiments according to Figures 3 and 4, the outer contour of the rotor 11 and the stator 10 have an arching directed inwards.
 5 Experiments and calculations have yielded the result that, due to this measure, improved, i.e., disruption-free, gas flow through the pump 2 can be achieved.

It is particularly expedient if the stator 10 and the outer contour of the rotor 11 have a hyperbolic curve. The result of this measure is the following calculation:

10

Following a greatly simplified approach to the description of the mode of function of a threaded pump, one can, ignoring slip effects and gap back-flow, write the following equation:

15

[See source, Page 7 for equation.]

$$q = \frac{zhUa \cos \alpha}{2\left(1 + \frac{s}{h}\right)} p - \frac{zh^3 a p}{12\eta} \frac{dp}{dx}$$

with

20

z number of channels
 h thread depth
 U circumferential speed
 a channel width
 α thread pitch
 s gap between the upper edge of the thread web and the stator
 p averaged pressure in a small area dx of the thread
 25 η dyn. viscosity
 q gas flow

30

The first term describes the Cuette flow while the second term describes the channel back-flow arising due to the pressure gradient. All the geometry data, with the exception of the channel depth, can be assumed as essentially constant over the axial length. Furthermore, the denominator in the first term is approximated by 2 since the ratio s/h is rather small. Also, the viscosity is approximated as a quantity independent of pressure.

One can thus write:

[See source, Page 8 for equation.]

5

$$q = Ahp - Bph^3 \frac{dp}{dx}$$

or

[See source, Page 8 for equation.]

$$\frac{dp}{dx} = \frac{A}{Bh^2} - \frac{q}{Bph^3}$$

10

This means there is, for a predefined pressure p and gas flow q , a certain channel depth h at which the pressure gradient is maximal. This optimal channel depth can be found by the differentiation of dp/dx by h :

[See source, Page 8 for equation.]

$$\frac{d}{dh} \left(\frac{dp}{dx} \right) = 0 = -\frac{2A}{3h^3} + \frac{3q}{Bph^4}$$

15

or also

[See source, Page 8 for equation.]

$$h_{opt}(x) = 9q / 2ABp(x)$$

20

In the case of a linear pressure curve in the pump, in a coordinate system with the axis of rotation 15 as χ -axis, a hyperbolic curve for channel depth over the axial length of the rotor thus results, and, in fact, in such a manner that the slope of the hyperbola decreases from the suction side to the pressure side. The position of the χ -axis and the γ -axis are indicated in Figure 3. This behavior is also confirmed by simulation by means of CFD software, which shows a weaker pump capacity of the rotor when its outer contour is conical or even cylindrical. Since, with an optimal rotor design, the mass, and thus the use of frictional surfaces, is automatically minimized, it is possible to drive, in direct comparison, higher gas throughputs.

25

In this calculation the form of the rotor hub 12 was initially not taken into account. It can be formed to be cylindrical, conical, or arched outwards, as represented in Figures 1 to 4. From the point of view of simple manufacture, the conical form (Figure 2) is to be preferred. From the point of view of a possible
5 disruption-free flow, a slight arching inwards, expediently also hyperbolic, is expedient.

The invention has been described with reference to the preferred
embodiments. Modifications and alterations may occur to others upon reading and
understanding the preceding detailed description. It is intended that the invention be
10 constructed as including all such modifications and alterations insofar as they come
within the scope of the appended claims or the equivalents thereof.

~~EVACUATION DEVICE~~

CLAIMS:

Having thus described the preferred embodiments, the invention is now
claimed to be:
